- The analysis of segregation has been carried out only for R genes for which associated markers were available.
- Several seed parents are missing in the cross combinations with the different R parents.
- In all cross combinations, gametes carrying no resistance gene were excluded from the segregation analysis, because the cross populations were phenotypically screened before the molecular screening and susceptible plants were discarded. See Material & Methods for details.
- 'Expected' stays for expected frequency for each gamete, excluded that one that does not carry any R locus. The analysis of segregation was possible because R loci were carried only by R parents that were heterozygous at all R loci, while seed parents did not carry any resistance, except 'Di Corone' that carried the Rvi6 gene and for which the segregation analysis was a little bit different.
- 'Di Corone', was initially included among the susceptible seed parents. During the experiment it was identified as synonymous of 'Prima', a selection from the PRI program and indeed carried the Rvi6 (=Vf) gene. The segregation analysis was carried out accordingly.

**Supplementary Table 4.** Observed segregation in the progeny of the R genes Rvi2, Rvi4, and Rvi6 from GK13.

| Seed parent            | Rvi2              |                   |                   | Rvi4              |                   |                   | Rvi6              |                   |                   | Total R | Segregation model | Expected unit frequency | $\chi^2$ | P value |

- The analysis of segregation has been carried out only for R genes for which associated markers were available.
- Several seed parents are missing in the cross combinations with the different R parents.
- In all cross combinations, gametes carrying no resistance gene were excluded from the segregation analysis, because the cross populations were phenotypically screened before the molecular screening and susceptible plants were discarded. See Material & Methods for details.
- ‘Expected’ stays for expected frequency for each gamete, excluded that one that does not carry any R locus. The analysis of segregation was possible because R loci were carried only by R parents that were heterozygous at all R loci, while seed parents did not carry any resistance, except ‘Di Corone’ that carried the Rvi6 gene and for which the segregation analysis was a little bit different.
- ‘Di Corone’, was initially included among the susceptible seed parents. During the experiment it was identified as synonymous of ‘Prima’, a selection from the PRI program and indeed carried the Rvi6 (=Vf) gene. The segregation analysis was carried out accordingly.

**Supplementary Table 6.** Observed segregation in the progeny of the R gene Rvi6 from Golden orange.

- The analysis of segregation has been carried out only for R genes for which associated markers were available.
- Several seed parents are missing in the cross combinations with the different R parents.
- In all cross combinations, gametes carrying no resistance gene were excluded from the segregation analysis, because the cross populations were phenotypically screened before the molecular screening and susceptible plants were discarded. See Material & Methods for details.
- ‘Expected’ stays for expected frequency for each gamete, excluded that one that does not carry any R locus. The analysis of segregation was possible because R loci were carried only by R parents that were heterozygous at all R loci, while seed parents did not carry any resistance, except ‘Di Corone’ that carried the Rvi6 gene and for which the segregation analysis was a little bit different.
- ‘Di Corone’, was initially included among the susceptible seed parents. During the experiment it was identified as synonymous of ‘Prima’, a selection from the PRI program and indeed carried the Rvi6 (=Vf) gene. The segregation analysis was carried out accordingly.
