ECO-INNOVATION IN VALCUCINE FOR A CIRCULAR ECONOMY

Veronica Novelli*, Paola Geatti, Luciano Ceccon, Alberto Bettarel

*Department of Economics and Statistics, University of Udine, Via Tomadini, 30/A, 33100 Udine,
Italy*

Abstract

Enterprises consider sustainability as an opportunity of communicating working methods and virtuous behaviors they adopt in the optics of sustainable development, and that allow both to improve their image in the market and to implement the relationships with stakeholders, thus strengthening their role on the territory. Valcucine is an enterprise of the Livenza furniture district located in the municipality of Pordenone (Italy). Valcucine focuses its care in the production of furniture, in particular of kitchen units, which are characterized by sustainable production, by eco-compatibility of materials and by the lowest possible environmental impacts. Valcucine wishes to transfer its enterprise philosophy to customers by improving product quality, by rationalizing the use of recyclable virgin raw materials, by employing also recycled materials and by reducing dangerous emissions into the environment. For this reason, Valcucine has obtained several certifications, such as ISO 14001, Forest Stewardship Council (FSC), F**** and Leadership in Energy and Environmental Design (LEED). In particular, the LEED certification, which has been obtained for the Invitrum and Meccanica production lines, allows the enterprise to differentiate from the competitors and to enter new segments of the market, such as the market of the Arab countries, where the LEED certification is renowned and appreciated. A substantial differentiation of this kind gives a competitive advantage to the enterprise working in a field which has been saturated for many years and represents a strength point, particularly in present economic framework. This virtuous behavior of the enterprise fits well into the principles inspiring circular economy and perfectly embraces the Goal 9.4 of the Sustainable Development (Agenda 2030), which foresees a sustainable industrial development, with the adoption of technological solutions in the optics of environment and people safeguard.

Key words: formaldehyde emissions, FSC, ISO 14001, LEED certification, Valcucine

34 **1. Introduction**

35

36 Agenda 2030 is a global strategic action plan subscribed in September 2015 by the
37 governments of 193 countries, UN members. It consists of 17 goals for Sustainable Development to
38 be achieved within 2030. Goal 13 is represented by the fight to climate changes caused by
39 environmental pollution due to vehicular traffic, heating systems and industrial activities (Agenda
40 2030, 2015).

41 In 2016, the “Paris Agreement” on climate changes entered into force, addressing the main
42 priority to limit the rise of global temperatures (Sustainable Developments Goals, 2017). In fact,
43 Earth has warmed within the last 150 years, especially during the last six decades (Jones et al.,
44 1999). Many studies have been published on the causes and the consequences of the increase of
45 global temperature (Crowley, 2000; Mitchell, 1989; Overpeck et al., 1997). Indeed, every time we
46 decide to buy a good, we have the opportunity to offer our own contribution for the environmental
47 protection and for saving raw materials and energy sources, and finally we can contribute to the
48 climate change. Therefore, proper materials and processes used in any industrial sector allow to
49 improve the environmental performances of the enterprises, which can obtain voluntary
50 certifications, introducing them in the market of green and ecological products and services, also
51 having economic benefits, (Bovea and Vidal, 2004; Ying and Li-jun, 2012).

52 Use of secondary raw materials and renewable energy sources, saving of water, fuel
53 consumption and waste production enable enterprises to be virtuous in the perspective of circular
54 economy, Goal 9.4 of Agenda 2030. The linear concept of economy is so exceeded by the new
55 concept of circular economy, which represents a continuous and positive development cycle: it is a
56 regenerative economy, reproducing nature, optimizing the systems connected each other
57 (Ellen MacArthur Foundation, 2017; Federico, 2015). In few words, circular economy minimizes
58 the consumption of resources by the adoption of cleaner technologies (Andersen, 1997; Andersen,
59 1999) and the application of the BAT (Best Available Technologies).

60 Eco-efficient companies are able to match their economic interest taking care of the
61 environment, producing more, taking less from the environment, by recycling and saving resources
62 and energy, obtaining new competitive advantages and a better position on the market (Shrivastava,
63 1995; Testa et al., 2011). Among the voluntary environmental instruments there are LCA, Eco-
64 labelling, ISO 14001, LEED certification, F**** certification.

65 In the Friuli Venezia Giulia region (Italy) there are two important furniture districts: the
66 Livenza district, in the province of Pordenone, and the chair district, in the province of Udine.
67 Furthermore, Catas (an Italian institute for the certification, research and tests for the furniture
68 sector), the most important laboratory in Europe for testing and researching on furniture quality, is

69 located in San Giovanni al Natisone, in the province of Udine, as well. During the meetings of
70 Sustainability at Ecomondo 2017, a congress session has been dedicated to indoor air quality, where
71 Catas presented a report on the characterization of emissions by domestic furniture. Fireplaces with
72 particulate matter, cigarette smoke, dust, food cooking, can pollute indoor air in close spaces, but
73 also building materials and furniture may cause emissions of dangerous substances for human
74 health. Volatile organic compounds (VOCs) are easily released into air and this process has an end,
75 while formaldehyde is continuously emitted because it is generated inside the panels (Bulian and
76 Fragassa, 2016). Many epidemiological studies on cancer risk for humans classified formaldehyde
77 as “probably carcinogenic to humans” (IARC, 1982, IARC, 1987; IARC, 1995), while the most
78 recent studies defined formaldehyde as “carcinogenic for humans” (Cogliano et al., 2004; Cogliano
79 et al., 2005; IARC, 2006).

80 The aim of this paper is to present the case study of Valcucine, a company operating in the
81 Livenza district, which was able not only to improve the environmental quality of the territory in
82 which it is located, but also to enter markets in which the care towards environmental and health
83 protection is particularly real.

84

85 **2. Materials and Methods**

86

87 Data and information, relative to the case study, were collected by interviews with the
88 persons in charge of the communication and of the quality control of the company.

89

90 **3. Case Study Presentation**

91

92 Valcucine is an enterprise of the Livenza furniture district located in the municipality of
93 Pordenone (Italy). Valcucine makes modular kitchen units and other wood furniture destined to
94 customers of a medium-high target. Exports represented 40% of sales in 2014, thanks to the
95 company policy of growth of its catchment area. Valcucine carries on the only activity of planning
96 and assembly of the components, with some additional workings on the semi-finished boards such
97 as drilling, sectioning, beading and customization of worktops. The enterprise has concentrated on
98 the topics of sustainability and of protection of customers’ health, by devoting attention in particular
99 to:

- 100 - shortage of raw materials,
- 101 - management of waste and of products at the end of their life cycle,
- 102 - energy consumption,
- 103 - environmental pollution.

- 104 The goals of Valcucine are:
- 105 - the decrease of consumption of both energy and virgin raw materials employed in the
 - 106 production process,
 - 107 - the decrease of the use of dangerous materials,
 - 108 - the development of technological innovations directed to environmental safeguard.

109

110 **4. Results and Discussion**

111

112 The guidelines of Valcucine's management are:

- 113 1. Product dematerialization: Valcucine obtained a notable saving of wood, of rolled sections and
114 of energy in particular by reducing the thickness of the "Riciclantica" mono-material aluminium
115 door to only 2 mm. From the managerial point of view, this policy aiming at dematerialization
116 led to reduce storage spaces, weight of finished products, energy consumption and waste
117 production.
- 118 2. Material recyclability, by introducing recyclable materials, as glass and aluminium, and recycled
119 components for structural pieces in its products. With a view to reuse at the end of the life cycle,
120 Valcucine plans its products so that the components can be easily identified and separated at the
121 time of discarding (Bergamaschi, 2010). Product components are assembled with mechanical
122 joints, without employing glues or adhesives, to be easily disassembled and recycled. This fact
123 allowed Valcucine to commit itself in the free collection of its products at the end of their life
124 cycle. The aluminium components, which are present in the structural frames of the doors and in
125 the supports of worktops, are completely recyclable. Their reclamation is economically
126 advantageous, since energy needed to obtain recycled aluminium is about 5-10% in respect of
127 energy needed to obtain primary aluminium from ores (Quinkertz et al., 2001; Smith, 2006).
128 Plastic components are labelled to favour their identification and possible reuse at the time of
129 discarding. Furthermore, Valcucine has committed itself in reclamation of doors and their
130 components, as rolled stratified section boards, which are reused for the production of
131 dashboards in the car field when they are cast-off. In 2009, Valcucine was able to make a kitchen
132 unit which is 100% recyclable and 80% reusable thanks to the use of the Invitrum glass
133 structural basis, together with a glass worktop with an aluminium support and the "Riciclantica"
134 door (Galli, 2015). The characteristics of recyclability and reusability of some components made
135 by Valcucine are shown in Table 1.

136

137 **Table 1.** Characteristics of recyclability and reusability of some components made by Valcucine

138

Component	Material	Characteristics
Draw plates	Recycled aluminium	100% recyclable, 80% reusable
Backs	Primary aluminium sheets	100% recyclable, 100% reusable
Legs	Recycled iron, plastic	100% recyclable
Bottom bases (structural area/part)	Temperated glass	100% recyclable, 90% reusable
Sides	Temperated glass	100% recyclable, 90% reusable
Spacers	Recycled aluminium	100% recyclable, 100% reusable

139

141

142 3. Reduction of dangerous emissions. Valcucine has identified in particular three aspects to be
143 monitored:

- 144 - varnishes containing synthetic solvents,
- 145 - artificial radioactivity,
- 146 - formaldehyde emissions.

147 Furniture treated with varnishes containing synthetic solvents continues to emit harmful
148 substances for a long time after buying, with risks for health of final users. To limit solvent
149 emissions, Valcucine uses water varnishes, by realizing a superficial finish based on oils and natural
150 polishes.

151 Artificial radioactivity is due to the radioactive substances emitted into the environment by
152 the accidents of nuclear plants, which can be absorbed by trees and subsequently be released during
153 time by wood. For this reason, Valcucine carries on analyses to check the presence of radioactivity
154 in the timber utilized.

155 In the sector of wood processing, the wood elements for obtaining panels, like chipboard,
156 plywood and laminated wood, are stucked by resins and adhesives based on urea-formaldehyde,
157 melamine-formaldehyde and melamine-urea-formaldehyde. The risk of formaldehyde inhalation
158 regards initially the workers during the steps of pressing, pasting, varnishing, handling and
159 management. Anyhow, formaldehyde emissions continue for years, with potential risks for
160 consumers' health, and contribute to generate the so called "indoor pollution". Valcucine does not
161 carry out panel realization, which is the step characterized by the highest release, but only handles

162 the semi-finished products. Furthermore, Valcucine realizes final products without chipboard,
163 thanks to the use of high pressure laminates; however, frames made by melamine-faced particle
164 boards are used for some kitchen units, which respect standards and limits imposed by the Japanese
165 F***** normative, the most severe in the world.

166 4. Product durability: Valcucine products are planned to last for a long time, with a consequent
167 reduction of environmental impacts. Valcucine adopts the principles of eco-innovation, which is
168 defined “the production, the introduction or the use of a product, a process, a service, a management
169 system, or a company methodology which is new for the company itself or for consumers, and
170 which guarantees, during its life cycle, a reduction of environmental risk, of pollution and of other
171 negative impacts due to the use of resources (including energy) with respect to other possible
172 expectations.” (Sala and Castellani, 2011; Sustainable Development Goals, 2017). The process
173 foresees the promotion of environmental efficiency with two modalities:

- 174 - by activating an efficient use of resources without exceeding the so called “carrying
175 capacity” (Daily and Ehrlich, 1992; Fearnside, 1997; Rees, 1992); an example of carrying
176 capacity can be the removal of wood from a woodland, guaranteeing that the same wood
177 amount will remain unaltered during time,
- 178 - by adopting innovations allowing to increase the carrying capacity of an eco-system, by
179 producing the necessary resources for its living species, without risks for the survival of
180 present and future population (Milardi, 2015).

181 Therefore, the concept of eco-innovation includes the whole of the methodologies,
182 instruments, technological, organizational and logistic options which allow a company to make
183 more sustainable its products and processes.

184 The eco-innovation application to the planning step is called eco-design and is finalized to
185 improve all the aspects related to a product, from the provenance of raw materials to the final
186 packaging, through all the phases of product life cycle (Radonjič et al., 2015).

187 Concretely, Valcucine participates in financing of reforestation by respecting original eco-
188 systems, by providing, in some cases, for buying the interested earths and by establishing
189 connection with the developing countries, with whom campaigns of sensitization and information
190 have been set up, in the perspective of an equilibrate use of resources.

191 Because of this procedure, it is possible to obtain many advantages:

- 192 - reduction of costs by a less material and energy consumption, less penalties due to a
193 measured pollution, reorganization of production processes and improving of the
194 relationships with providers;
- 195 - reduction of costs by a more successful management of human resources and an increasing
196 of work productivity;

- 197 - increasing of the income due to innovation and development of eco-friendly products,
- 198 recycling of products and scrape materials;
- 199 - creation of connection with local economies and undertaking of local people;
- 200 - construction of reputation due to increasing of efficiency and environmental responsibility;
- 201 - expansion of human capital due to a better management of resources.

202 As a consequence of the policy adopted by the company, Valcucine has obtained notable
 203 improvements, in particular in terms of reduction of consumption of raw materials, working scraps,
 204 waste production, emission of harmful substances and energy consumption. This has allowed the
 205 achievement of some environmental certifications.

206

207 *4.1 Certifications obtained*

208

209 *4.1.1 ISO 14001*

210

211 In 2001 Valcucine obtained the ISO 14001 certification. The parameters monitored by the
 212 environmental management system are: water consumption, electricity consumption, fuel
 213 consumption, use of raw materials, use of chemicals, emissions into the atmosphere, waste
 214 management and indirect environmental aspects.

215 Water consumption. Water is not used for the production process, but only for sanitary use
 216 and for irrigation of the green areas of the plant. Water consumption in the period 1999-2016 is
 217 presented in Table 2. As can be noted, consumptions showed significant yearly variations. It is not
 218 possible to control the consumption of water for irrigation, which substantially depends on
 219 atmospheric precipitations, whereas the reduction of consumption of sanitary water has been
 220 achieved with a careful maintenance of supply facilities.

221

222 **Table 2.** Water consumption (m³) in Valcucine plant

223

Year	1999	2000	2001	2002	2003	2004	2005	2006	2007
Consumption	12488	13365	12790	6811	4836	4403	4635	7459	5620

224

Year	2008	2009	2010	2011	2012	2013	2014	2015	2016

227

228 Electricity consumption. In 2010 the lighting installation of production departments was
 229 rationalized. Furthermore, in 2010 the installation of photovoltaic panels (1450 m²) was completed,
 230 as well. Electricity consumption, including the requirements of the manufacturing process, offices
 231 and other operational activities, is presented in Table 3.

232
 233 **Table 3.** Electricity consumption (kWh) in Valcucine plant
 234

Year	Electricity from the grid	Electricity produced by the photovoltaic plant	Self-consumed electricity	Total consumption
1999	586266			586266
2000	596000			596000
2001	638200			638200

 237

238 Fuel consumption. Until winter 2009-2010, diesel oil was used to heat the plant; since the
 239 following year, diesel oil has been replaced by natural gas. Natural gas is also used in the laboratory
 240 for material testing. Fuel consumption relative to the period 1998-2016 is reported in Table 4.

241
 242 **Table 4.** Fuel consumption in Valcucine plant

Season	Year	Diesel oil (L)	Natural gas (m ³)
1998/1999		65000	
1999/2000		74000

244

245 Source: Valcucine, 2017, personal communication

246

247 Use of raw materials. The main materials are chipboard and fibreboard panels, laminated
 248 wood panels, glass, aluminium and steel, which come to the company as semi-finished materials.
 249 The planning activity is addressed to reduction of not-renewable raw material consumption and to
 250 employment of composite materials which, despite being characterized by a high energy
 251 consumption for their production (glass, aluminium and steel), have a long life cycle and a complete
 252 recyclability.

253 Use of chemicals. The main products used are solvents, bonding agents and adhesives. The
 254 used amounts have not varied much over years, and are so low, that the risk associated may be
 255 classified as irrelevant for the safety of workers and the effects on the environment.

256 Emissions into the atmosphere. As regards the exposure of Valcucine workers to wood dust,
 257 measurements carried out in 2014 in 10 workstations showed amounts included in the range 0.10 –

258 0.65 mg/m³, below the limit value of 5 mg/m³ (EC Directive, 2004). Nevertheless, wood dust
259 produced during the manufacturing process is captured by an air extraction and filtration equipment
260 and then disposed, in order not to be released into the atmosphere.

261 Waste management. Packaging originates mainly from kitchen equipment suppliers'
262 wrappings and are composed mainly of paperboard and plastics (PE, PS and PET). Glass, granite,
263 aluminium and steel are also present in discarded materials, both as processing waste and as parts
264 coming from kitchen furniture taken back from customers when disused, or when old or defective
265 parts are substituted. Moreover, Valcucine produces electric and electronic equipment waste
266 (EEEW) because it assembles and disposes components for lighting. Hazardous waste is produced
267 as the result of the use of varnishes, mostly water paints, and oils and emulsions for machine tools,
268 compressors and pantograph maintenance.

269 Indirect environmental aspects. Valcucine purchases semi-finished materials from external
270 suppliers, who manage all phases from raw material acquisition up to painting. Consequently,
271 Valcucine asked suppliers improvements in environmental matters, in particular with regard to: the
272 reduction of industrial solvents in varnishes, with the use of water paintings, for all wood and glass
273 panels since 2005; the use of components with extremely low formaldehyde emissions; the use of
274 sustainable, FSC-certified, timber. Valuable information are collected for each supplier to monitor
275 its environmental performances; gathered data are used to set an "indirect environmental impact"
276 value, which might constitute a parameter for the qualification of suppliers.

277

278 4.1.2 *FSC chain of custody certification*

279

280 Valcucine uses wood as the main material in the realization of its products. The company is
281 not involved in wood processing, except marginally in short finishing operations: it mostly
282 purchases semi-finished products as doors, panels, seat backs, structural parts and accessories from
283 external suppliers (Valcucine, 2017, personal communication).

284 With the aim of maintaining a high product quality and protecting the environment,
285 Valcucine started the FSC chain of custody (FSC-CoC) certification process. To obtain the
286 certification, all production phases along the supply chain need to be identified, to ensure the
287 traceability of the material; so it is necessary to identify in an appropriate matrix the following
288 issues: type of incoming material, supplier from which material is purchased and validity of
289 supplier certification, type of incoming material certification (e.g. FSC 100%; FSC Mix Credit,
290 etc.), contractor chosen by the supplier for possible processing and kind of processing, type of
291 certification which will be affixed on the product at the end of processing or after assembling.
292 Likewise, the material supplier has to fill out a similar matrix by indicating previous phases, up to

293 the phase of wood cutting, in order to guarantee traceability and certification characteristics
294 (Masiero and Zorzi, 2006).

295 An important topic is the allocation of certification standard of finished products - output -
296 (FSC 100% or FSC Mix Credit) in relation to incoming products – input -. FSC regulation provides
297 for three types of assessment systems based on: 1. the type of transferred materials, 2. the
298 percentages of certified and not certified materials, 3. assigned credits (rare).

299 In case of a single type of material, the initial label is assigned to the final product. In the
300 other cases, the FSC certification of the final product changes on the basis of the percentage of
301 incoming material of one or more types: the allocation is done with a weighting of incoming
302 material. Valcucine properly evaluated this issue because of small not certified parts (a very small
303 proportion of the overall amount), slowing down the whole certification process. On the occasion of
304 the various renewals of the certification, Valcucine has widened the range of certified products. In
305 2008, in compliance with the FSC STD-40-004 standard, Valcucine obtained the FSC 100%
306 certification for solid maple pieces, corresponding to the so-called “internal drawer”. In 2014 the
307 FSC 100% certification was obtained for doors and back panels, as well as the FSC Mix for parts
308 made of melamine faced chipboard panel (material which is normally used for cabinet sides and
309 bottom panels) (Valcucine, 2017, personal communication). The products which obtained the
310 certification are listed in Table 5.

311

312 **Table 5.** Present FSC certified Valcucine’s products

313

Product	Certification
Internal solid maple drawer	FSC 100%
Door	FSC 100%
Cabinet back panel	FSC 100%
Cabinet side panel, cabinet bottom panel, wooden worktop	FSC Mix

314

315 Source: Valcucine, 2017, personal communication

316

317 Special investments were not needed for the certification process of Valcucine’s products;
318 costs met were mainly related to consultancy services and certification process itself. Because of
319 FSC certification, which led to an improved product quality and facilitated access to markets in
320 which FSC-CoC standard is a compulsory element and competition is reduced, the company
321 improved its environmental sustainability reputation.

322

323 4.1.3 *The F**** certification*

324 4.1.3.1. *Formaldehyde: indoor air quality and effects on human health*

325 We spend the major part of our life inside houses, offices, schools etc., so indoor air quality
326 (IAQ) we breathe is very important. Many chemical substances can be emitted by furniture, walls,
327 carpets, with dangerous consequences for human health. Modern buildings, built with energy saving
328 insulating systems, could increase the concentration of pollutants in indoor environments. In
329 particular, formaldehyde and other substances can be released in times.

330 In the European countries, the national regulations for construction products are different
331 among them, and this can create some problems when firms have to export their products from a
332 country to another (Bulian and Fragassa, 2016).

333 Formaldehyde is a colourless gas with an acrid odour; it is used in many industrial
334 productions, like adhesives for wood, floorings, paints, walls, ceilings, carpets, furniture, plastics
335 and textiles and for producing chemical compounds (Bosetti et al., 2008; Missia et al., 2010).
336 Formaldehyde emissions are dangerous not only during the phases of working, but also during the
337 phase of product use (National Cancer Institute, 2017).

338 In the last years, IAQ has become a very important matter under discussion (Böhm et al.,
339 2012; de Blas et al., 2012; Gilbert et al., 2006; Mølhave et al., 1995; Vassura et al., 2015). The
340 frame study European Indoor Air Monitoring and Exposure Assessment (AIRMEX) is related to the
341 bond between indoor air and chronic human exposure to VOCs in public buildings during the
342 years 2003-2008 (Geiss et al., 2011; Kotzias, 2005).

343
344 4.1.3.2. *Wooden panels: the European and Japanese normatives*

345
346 Wooden panels are classified on the basis of formaldehyde emissions, according to the
347 technical regulation UNI EN 13986 (appendix B). Panels can be classified in one of the two classes
348 E1 and E2. For E1 (low emissions) the beginning test refers to the emissions that have to be less or
349 equal to 0.124 mg/m³ air, measured with the chamber analysis method EN 717-1. The raw
350 panels, Medium-Density Fibreboard (MDF) or Oriented Strand Board (OSB), have to emit less or
351 equal to 8 mg/100g of oven dried panel, measured with the method UNI EN ISO 12460-5:2016.
352 The other panels, varnished panels, melamine-faced particle boards or plated panels have to emit
353 less or equal to 3.5 mg/m² h, measured with the gas analysis method EN 717-2, substituted by the
354 UNI EN ISO 12460-3:2015.

355 The E1 limit of emission (0.1 ppm) is in accordance with the limit recommended by WHO
356 (Federlegnoarredo, 2017).

357 According to the changes for improving the integrity of new houses, after the Kobe
358 earthquake in 1995, the Japanese government introduced some countermeasures for reducing indoor
359 formaldehyde pollution. In fact, the Housing Quality Assurance Act (HQAA) required the
360 improvement of the quality and performance of residential houses, including air quality. The Sick
361 House Regulations regulated formaldehyde emissions in houses, schools and clinics. Among the
362 countermeasures for formaldehyde emissions there was the F***** rating of materials for products,
363 including wooden building materials. For the F***** rating system, formaldehyde emission levels
364 have to be less or equal to 0.005 mg/m² h, an added value for the above mentioned wooden products
365 (Eastin and Mawhinney, 2011).

366

367 *4.1.3.3. Valcucine toxic emissions control (F***** normative)*

368 In October 2006, Valcucine obtained the F***** certification for its chipboard panels by
369 Catas (Valcucine, 2017). The panels observe the formaldehyde emission limits required by the
370 Japanese normative, which is the most severe in the world: this limit is less than the half of the
371 European standard E1 (Federlegnoarredo, 2017). In Italy, the Ministerial Decree of October 10,
372 2008, foresees a limit of 0.1 ppm, as recommended by WHO.

373

374 *4.1.4 The LEED certification*

375

376 The LEED (Leadership in Energy and Environmental Design) voluntary certification is
377 referred to a system of evaluation of the energy and environmental characteristics of a building, to
378 establish how much it integrates with the environment, by defining its level of eco-compatibility
379 during the steps of planning, building and management (Steinemann et al., 2017; Wei et al., 2015).
380 The system is based on the assignment of a score to each requisite which characterizes the building
381 sustainability. The degree of sustainability is obtained by the sum of the scores. Therefore, not only
382 the structural and plant-engineering components, but also the internal elements, as furniture and
383 kitchen unit, contribute to the definition of the degree of sustainability.

384 Valcucine had set itself entering the market of Arab countries as a goal; in that countries the
385 topics of eco-sustainability of buildings and the LEED certification are renowned and appreciated.
386 This is partly due to the local market habits of proposing the sale of buildings already furnished
387 inside. For this reason, who takes part in a LEED project in the Arab countries looks for suppliers of
388 products compliant with the parameters required for the awarding of the various scores. Therefore,
389 in 2013 Valcucine started the process of evaluation of some of its products with the aim of

390 awarding of LEED credits. The products to which LEED credits have been awarded belong to the
391 Invitrum and Meccanica models. The credits obtained by Valcucine are shown in Table 6.

392

393 **Table 6.** LEED credits obtained by Valcucine for the Invitrum and Meccanica models

EQ Credit 4.1_Low-Emitting Materials: Adhesives and Sealants

395

396 Source: Valcucine, 2017, personal communication

397

398 For many years Valcucine had already implemented an environmental management system,
399 with a consequent decrease of the utilization of raw materials and energy and of environmental
400 impacts. Therefore, Valcucine had to introduce only small changes to planning and making of its
401 products in order to obtain the LEED credits. As a consequence, the costs met have been essentially
402 only those of professional advice and certification, corresponding to about 4000 €. However, the
403 awarding of LEED credits to Valcucine's products has not led to significant increases of sales up to
404 now.

405

406 **5 Conclusions**

407

408 Valcucine, a company operating in the Livenza furniture district, carries out its activity with
409 particular care towards the environment. This policy allowed Valcucine to obtain some
410 certifications, such as ISO 14001 in 2001, F***** in 2006, FSC in 2008 and LEED in 2013.
411 Consequently, Valcucine could differentiate from the competitors and enter new segments of the
412 market. The virtuous behavior of Valcucine fits well into the principles inspiring circular economy
413 and perfectly embraces the Goal 9.4 of the Sustainable Development (Agenda 2030), which
414 foresees a sustainable industrial development.
